[Data & Apprentissage] Introduction à la science des données et à l'apprentissage

Nicolas Vayatis

Deep learning

"Big picture" of Learning

Machine Learning What we have seen so far

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Supervised machine learning Setup

- Data: (X₁, Y₁),..., (X₁, Y₁) with X_i being a vector of variables (factors) for observation i, and Y_i being the label of X_i
- Hypothesis class: set of functions $h \in \mathcal{H}$
- Loss of a function h at a data point (X, Y):

 $\ell(h(X),Y) \geq 0$

• *Empirical risk* of a function *h* over the data:

$$\widehat{L}_n(h) = \frac{1}{n} \sum_{i=1}^n \ell(h(X_i), Y_i)$$

Machine Learning Methods Principle

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

What is a Machine Learning Method:

- Problem characterized by three ingredients:
 - Loss
 - Hypothesis space
 - Regularization
- ML algorithm characterized by an optimization strategy to solve the minimization of regularized loss over the hypothesis space

- General hypothesis space with function selected through *Empirical Risk Minimization* (ERM) (could be shallow or deep)
- (Sparse) Linear models with parameters estimated through (penalized) least square minimization
- Kernel ridge regression Exercise: What are the hypothesis space, the loss, the regularization, and the optimization method in that case?

The latter is an example of popular and efficient shallow learning method.

Deep Learning: Introducing the main concepts

Deep Feedforward Network

Hypothesis space: functions of the form

$$h(x,\theta) = \sigma_m \circ A_m \circ \sigma_{m-1} \circ \dots \circ A_2 \circ \sigma_1 \circ A_1 x$$

where $\theta = (A_1, \ldots, A_m)$ sequence of parameters to be estimated through learning

• We denote by $\sigma = (\sigma_1, \dots, \sigma_m)$ the so-called activation functions which are hyperparameters related to the choice of a network architecture (which includes the number and size of the layers - see below).

Deep Feedforward Network

• Optimization objective (far from convex! where is the regularizer?):

$$\min_{\theta} \frac{1}{n} \sum_{i=1}^{n} \ell(h(X_i, \theta), Y_i)$$

• Optimization method based on stochastic gradient descent (iterates over data points)

$$\theta_{i+1} = \theta_i - \eta \frac{\partial \ell(h(X_i, \theta), Y_i)}{\partial \theta}(\theta_i)$$

Architecture: 1 kernel - 2 parameters

Goal for the class today

- Develop insights about deep learning and neural networks: when it works and when it does not work, and what it means to "work" (open discussion)
- Practical guide to deep learning optimization and engineering
- Learn about the three mysteries of deep learning... and connect to the machine learning concepts seen so far (such as approximation error, complexity, and regularization)

Historical perspective on neural networks

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

- Cybernetics (1940s-1960s)
 - Achievement: modeling and training one neuron
 - Key algorithm: Perceptron
 - Paper: Rosenblatt (1958)
- Connectionism (1980s)
 - Achievement: training one or two hidden layers
 - Key algorithm: Backpropagation
 - Paper: Rumelhart-Hinton-Williams (1986)
- Deep Learning (2007-....)
 - Achievement: training multiple layers of representation
 - Key algorithm: Stochastic gradient
 - Papers: Hinton (2006), Bengio-LeCun (2007)

Stone-Weierstrass theorem

 Consider any continuous function f : [a, b] → ℝ, then for any ε > 0, there exists a polynomial P such that:

$$\sup_{x\in[a,b]}|f(x)-P(x)|<\varepsilon.$$

Single-Layer Neural Network Definition

Single-layer neural network: Let σ

 a 'smooth' activation function. A
 single-layer neural network with N
 units and an activation function σ,
 is a function of this form:

$$h(x) = \sum_{k=1}^{N} \sigma(a_k^T x + b), \ \forall x \in \mathbb{R}^d$$

where $a \in \mathbb{R}^d$, $b \in \mathbb{R}$, N integer. The number N corresponds to the number of *units* in the hidden layer of the network.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Activation function Examples

|▲□▶ ▲圖▶ ▲≣▶ ▲≣▶ | ≣ | のへで

Single-Layer Neural Network are universal approximators

• Cybenko's theorem: consider any continuous function $f : [0,1]^d \to \mathbb{R}$, then for any $\varepsilon > 0$, there exists a single-layer neural network $h(x) = \sum_{k=1}^{N} \sigma(a_k^T x + b)$ (i.e. some *N*, *a*, *b*) such that:

$$\sup_{x\in [a,b]} |f(x) - h(x)| < \varepsilon .$$

Backpropagation algorithm:
 The key to multilayer perceptron calibration

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Multilayer perceptron More than one hidden layer!

 Hypothesis space: functions of the form

$$h(x,\theta) = \sigma \circ A_m \circ \sigma \circ \dots \circ A_2 \circ \sigma \circ A_1 x$$

where $\theta = (A_1, \ldots, A_m)$ sequence of parameters to be estimated through learning and σ activation function applied componentwise

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 のへの

Backpropagation Principle

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

• Consider the square loss, then given a weight vector θ_1 , we can evaluate the error as:

$$\mathcal{L}(\theta_1) = \frac{1}{n} \sum_{i=1}^n (h(X_i, \theta_1) - Y_i)^2$$

 The idea is to propagate the error backwards in the network to update θ₁ by the following rule:

$$\theta_2 = \theta_1 - \eta \nabla_\theta \mathcal{L}(\theta_1)$$

where η is the so-called learning rate.

Optional material Computing the gradient with Backpropagation

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Backpropagation Background: Chain rule

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

• Consider the composition of three functions:

$$f(u) = \ell \circ \sigma \circ g(x)$$

with $t = \sigma \circ g(u)$ and z = g(u) (everything in \mathbb{R} here)

• The chain rule provides the expression for the derivative of f:

$$\frac{df}{du}(u) = \frac{d\ell}{dt}(t)\frac{d\sigma}{dz}(z)\frac{dg}{du}(u) = \ell'(\sigma \circ g(u))\sigma'(g(u))g'(u)$$

Backpropagation Background: Activation function

• Typical examples:

• For the logistic activation function: $\sigma(z) = \frac{1}{1 + e^{-z}}$, we have by standard algebra:

$$\sigma'(z) = rac{d\sigma}{dz}(z) = \sigma(z)(1 - \sigma(z))$$

Backpropagation Toy example: the single unit case

- Consider a single unit (neuron): h(x, a) = σ(a^Tx) which is connected to the output Y of the network
- The error of the predictions produced by this neuron on the training data is the following:

$$\mathcal{L}(a) = \frac{1}{n} \sum_{i=1}^{n} \ell(\sigma(a^{T}X_{i}), Y_{i})$$

where $\ell(t, y) = (t - y)^2$ considering the square loss here.

Backpropagation Gradient computation

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ のへぐ

- Apply the chain rule with three compositions in the case where the last function is linear
- The gradient of \mathcal{L} wrt *a* is given by:

$$\frac{\partial \mathcal{L}}{\partial a_j}(a) = \frac{1}{n} \sum_{i=1}^n \frac{\partial \ell}{\partial t} (\sigma(a^T X_i), Y_i) \sigma'(a^T X_i) X_{ij}$$

Backpropagation Weight update

Special case here: square loss, logistic activation function

$$rac{\partial \ell}{\partial t}(t,Y_i) = 2(t-Y_i) \ \, ext{and} \ \, \sigma'(z) = \sigma(z)(1-\sigma(z))$$

The gradient update applied at input 'neurons' is the following

$$\frac{\partial \mathcal{L}}{\partial a_j}(a) = \frac{2}{n} \sum_{i=1}^n (z_i - Y_i) z_i (1 - z_i) X_{ij}$$

where $z_i = \sigma(a^T X_i)$

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ ● □ ● ● ● ●

End of optional material

From shallow to deep networks 1. How to build deep networks

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Engineering of deep learning

• Software environments for deep learning designed as computational graphs (Theano, Keras, TensorFlow...)

- A computational graph is a way to represent a math function in the language of graph theory.
- In a computational graph nodes are either input values or functions for combining values.

Edges receive their weights as the data flows through the graph. Outbound edges from an input node are weighted with that input value; outbound nodes from a function node are weighted by combining the weights of the inbound edges using the specified function.

Regularization in deep learning and why DL theory is difficult

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Implicit in the objective, but lots of engineering tricks in the computational graph:

- Weight decay
- Weight sharing
- Early stopping
- Model averaging
- Dropout
- Data augmentation
- Adversarial training

- Denote by T the structural parameters of the deep network (architecture, activity functions, regularization modes...) and \hat{f}_T the function produced by deep learning given T
- Some estimate of the predictive error L(f_T) of the function supposed to be available (can be estimated by hold out, cross validation...).
- Finding *T* is key to address the estimation-approximation tradeoff

- Selecting the structure of a deep network is a meta-learning problem
- The optimal architecture can be obtained if it is possible to solve the following optimization problem:

$$\min_{T} \hat{L}(\hat{f}_{T})$$

which is generally nonconvex, nonsmooth

• Main approaches to find *T*: experience, heuristics, discrete optimization, experimental design?

From shallow to deep networks2. The mysteries of Deep Learning

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Mysteries about deep learning

- Approximation: deep better than shallow?
- Optimization: nonconvex with millions of dimensions (!)
- Overfitting: huge complexity

Facts about approximation theory

Comparison of Shallow vs. Deep Networks

- Poggio and Liao (2018): approximation of compositional functions
- Liang and Srikant (2017): approximation of polynomial functions
- Similar findings:

" the number of neurons needed by a shallow network to approximate a function is exponentially larger than the corresponding number of neurons needed by a deep network for a given degree of function approximation."

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Facts about optimization in Deep Learning

• Under certain conditions, no poor local minima

- SGD avoids bad critical points
- Larger networks are better behaved (local minima are global)
